# A Comparative Analysis on the Model Adequacy of Four Transformation Techniques 

Anosike Joseph Ugonna \& Ogoke Uchenna Petronilla<br>Department of Mathematics and Statistics<br>University of Port Harcourt<br>Choba, Port Harcourt, Nigeria<br>Email:juanohugo@gmail.com; uchenna.ogoke@uniport.edu.ng

#### Abstract

This study compared four different transformation techniques by applying a simple linear regression on raw and transformed data. The $R^{2}$ of each model was obtained and a test on the significance of these $R^{2}$ was carried out. Also, the $r_{x y}$ (coefficient of correlation) were also obtained. The data used is a secondary data consisting of 53years (1964-2016) of the infant mortality rate in Nigeria (https://www.ceicdata.com/en/nigeria/health-statistics/ng-mortality-rate-infant-per-1000-live-births). The $r_{x y}$ were also compared and the results, $95.8 \%, 95.8 \%, 96.2 \%, 93.0 \%$, and $92.9 \%$ respectively. The $\mathrm{R}^{2}$ obtained for the raw data, logarithm, square-root, square and inverse are as follows: $91.8 \%, 91.7 \%, 92.5 \%$, $86.6 \%$ and $86.4 \%$ respectively. However, the $R^{2}$ obtained for the raw data, logarithm, square-root, square and inverse compete favourably but the performance of inverse transformation suits the data most in terms of model accuracy.

Key Words: Transformation, Raw data, logarithm, square-root, square, inverse

## I. INTRODUCTION

Data transformation is a process of converting data or information from one format to another, usually from the format of source system into the required format of a new destination system. There are a great variety of possible data transformations, from adding constants to multiplying, squaring, or raising to a power, converting to logarithmic scales, inverting, taking the square root of the values and even applying trigonometric transformation such as sine wave transformation. Simple linear regression captures the linear relationship between the expected value of Y and an independent variable say X . If linearity fails to hold, even approximately, it is sometimes possible to transform either the independent or dependent variables in the regression model to improve linearity. When fitting a linear regression model, one assumes that there is a linear relationship between the response variable and each of the explanatory variable. However, in many situations there may instead be a non-linear relationship between the variables.

This can sometimes be remedied by applying suitable transformation to some (or all) of the variables. Transformations can be used to correct violations of assumptions such as constant error variance and normality. The primary reasons for data transformation, as they are used for improving the compatibility of data with assumptions underlying a modelling process include viz: to stabilize the variance of the dependent variable, to normalize and linearity. Many statistical procedures assume that the variables are normally distributed. A significant violation of the assumption of normality can seriously increase the chance of the researcher committing either a type I or II error (depending on the nature of the analysis and the non-normality). However, Mecceri (1989) points out that true normality is exceedingly rare in education and psychology. Thus, one reason researchers utilize data transformations is improving the normality of variables. Zimmerman (1995, 1998) pointed the importance of normality in all statistical analysis whether parametric or non-parametric tests.

Two other reasons for non-normality are the presence of outliers and the nature of the variable itself. Judd and Clelland (1989) argued that outliers' removal is desirable, honest, and important. However, not all researchers feel that way (Orr, etal, 1991). Transformation can be useful to a researcher needing to know whether a variable's distribution is significantly different from a normal (or other) distribution (Rosenthal (1968), and Wilcox (1997)). Most people find it difficult to accept the idea of transforming data. Turkey (1977) probably had the right idea when he called data transformation calculation "re-expression" rather than "transformations Tabachnich and Fidell (200I) recommended transformation as a remedy for outliers and for failures of normality, linearity, and homoscedasticity, they are not universally recommended. Different techniques of transformation has been treated in different forms (see Mc Neil (1977),Velleman and Hoaglin, (198I) but this research aims to select the best technique to use in terms of model adequacy.

## 2. METHOD

The four (4) methods of data transformation techniques adopted is briefly explained using their mathematical formula.

## 2.I Different Transformation Techniques

The linear relationship assumed in the preceding analysis may be inappropriate in some problems. Indeed, non-linearities may be expected in the real world situations. Bearing in mind the complexity in analysis, model transformation becomes inevitable. This is to be able to use a regression model of simple forms in the transformed variables, rather than a more complicated one in the original variables. Some of the most common forms (and transformations) of non-linear models as used in this research are presented by the following polynomials.
i) $\quad y=\beta_{0}+\beta_{1 x}+\beta_{2} x^{2}+\ldots+\beta_{k x^{k}}+e$

This is usually called the curvilinear regression model.
Let $z_{i}=x^{i}, \quad(i=1,2, \ldots, k)$. Then
$Y=\beta_{0}+\beta_{1 z_{1}}+\beta_{2 z_{2}}+\ldots+\beta_{k z k}+e$
ii) $y=\beta_{0}+\beta_{|x|^{-1}}+\beta_{2} x_{2}^{-1}+\beta_{k x k^{-1}}+e$
let $z_{i}=x_{i}^{-1}$ (called inverse or reciprocal transformation), then

$$
\begin{equation*}
y=\beta_{0}+\beta_{1 z}+\beta_{2 z 2}+\ldots+\beta_{k z k}+e \tag{4}
\end{equation*}
$$

iii) $\quad y=\beta_{0} x_{1}^{\beta 1} x_{2}^{\beta 2} \ldots x_{k}^{\beta_{k}} e$

Taking logarithm of both sides (called the log-transformation), we have

$$
\begin{equation*}
\ln y=\ln \beta_{0}+\beta_{1} \ln x_{1}+\beta_{2} \ln x_{2}+\ldots+\beta_{k} \ln x_{k}+e \tag{6}
\end{equation*}
$$

Or equivalently $y^{\prime}=\beta_{0}{ }^{\prime}+\beta_{1}^{\prime} \mathrm{z}_{1}+\beta_{2}{ }^{\prime} \mathrm{zz}^{+}+\ldots+\beta_{k}{ }^{\prime} \mathrm{zk}^{+} \mathrm{e}$
iv) $y=\beta_{0}+\beta_{1} x_{1}^{1 / 2}+\beta_{2} x_{2}^{1 / 2}+\ldots+\beta_{k} x_{k}^{1 / 2}+e$
$z_{i}=x_{i}^{1 / 2} \quad$ (called the square root transformation)

$$
\begin{equation*}
y^{\prime}=\beta_{0}+\beta_{1 z}+\beta_{2 z 2}=\ldots+\beta_{k z k}+e \tag{9}
\end{equation*}
$$

v) Given a production function (say),
$\mathrm{y}=\left(\alpha_{1} x_{1}^{\rho}+\alpha_{2} x_{2}^{\rho}\right)^{v / \rho}$
on transformation, this gives the equation

$$
\begin{equation*}
y^{\rho / v}=\alpha_{1} x_{1}^{\rho}+\alpha_{2} x_{2}^{\rho} \tag{IO}
\end{equation*}
$$

Thus each observation on output (y) should be raised to the power of $\rho / v$ and each observation on capital ( $\mathrm{x}_{1}$ ) and labour input ( $\mathrm{x}_{2}$ ) are raised to power p . This is an example of power transformation of the variables.

Note: After transforming the variables, the usual method of estimating the parameters is employed

## 3. RESULTS

The results of this research will be presented in a tabular form which will be followed by the discussions on the tables listed.

Table I: Infant Mortality Rate for Nigeria, Number per I,000 Live Births, Annual

### 3.1 Test of $\mathbf{R}^{\mathbf{2}}$ Using F-Statistics

We test for the significance of $R^{2}$ using the $F$ - statistics.
$\mathrm{F}=\frac{R^{2} / k}{1-R^{2} / n-k-1} \sim \mathrm{~F}_{\mathrm{k},}, n-\mathrm{k}-1(\alpha)$; where, k is the number of regression coefficient or parameter, n is the number of observation., $\alpha$ is the evel of s significance.

### 3.2 Hypothesis

$H_{0}: R^{2}=0\left(R^{2}\right.$ Not significant) vs $H_{l}: R^{2}>0\left(R^{2}\right.$ is significant)
Using the given hypothesis, the raw data and the transformed data will be tested at $5 \%$ level of significance and the results presented on Table 2 below.

Table 2: TEST FOR THE SIGNIFICANCE OF R ${ }^{2}$

| TEST FOR THE SIGNIFICANCE OF R ${ }^{2}$ |  |  |  |  |

\& Contemporary Research in SCIENCE, ENGINEERING \& TECHNOLOGY Vol. IO. No. 3, September 2022

## 4. DISCUSSION

Table I shows the raw and transformed data which was fitted using SPSS software. The fits were examined using linear regression models, coefficient of determination (see appendix).
Table 2 shows the $R^{2}$ of the original data, log transform data, square-root transform data, square transform data data were $91.8 \%, 91.7 \%, 92.5 \%, 86.6 \%$, and $86.4 \%$ respectively. These results showed a clear picture in terms of the competitiveness in modeling (fitting) data. The linear regression model was obtained for the raw data set and the four different transforms. The respective $\mathrm{R}^{2}$ of data set were then examined to determine the total variation of the mortality rate explained by the changes in period (year). Obviously, the square-root transform had the highest of the $R^{2}$. Also considered was the test of normality for all the data set (see appendix). It was seen clearly that the square-root transform did not differ significantly from normality. It gave a more normal distribution from a skewness value very close to zero as required for a normal distribution than the rest of the data set. Furthermore, the correlation coefficient $r_{x y}$ was also considered for the raw data, log transform data, square-root transform data, square transform data, and the inverse transform data, the result were as follows; $95.8 \%, 95.8 \%, 96.2 \%, 93 \%, 92.9 \%$ respectively. Consequently, upon the results obtained from the foregoing, the square-root transformation is the best method of data transformation for the data used in this research.
