ABSTRACT

learned features, a down-sampling method (pooling) was used to reduce the size of the images. Performance metrics such as sensitivity, specificity and accuracy were used in evaluating the performance of the model. Experimental results show that the model performed well with classification accuracy of 98.57% which is relatively an improvement over the model that was used as a benchmark with 93. 35%. The confusion matrix reported 0 false positives (FP) and 14 false negatives (FN) on the test set. This implies that the model correctly predicted all images belonging to the right category as right irises, while it wrongly predicted 14 images belonging to the left category. Connotionally, it revealed that the right iris recorded higher accuracy compared to that of the left iris. Based on this performance, the research work establishes that the CNN based model is an improvement over existing models in the domain. Therefore, the model in no small measure will increase the efficiency of general biometric systems, security applications and will be of great assistance to the eye specialists. Researcher in future work shall consider the case of multiple classes and larger database.

Keywords: Iris image, Classification model, Deep Learning, Convolutional Neural network, Features

1. BACKGROUND TO THE STUDY

Iris recognition is a biometric method of identifying people based on unique patterns within the ring-shaped region surrounding the pupil of the eye. Every iris is unique to an individual, making it an ideal form of biometric verification (NEC, 2019).

According to George (2017), the iris is the colored ring component of the eye situated between the pupil and white sclera within the human eye. Figure 1 shows the anatomy of the human eye.

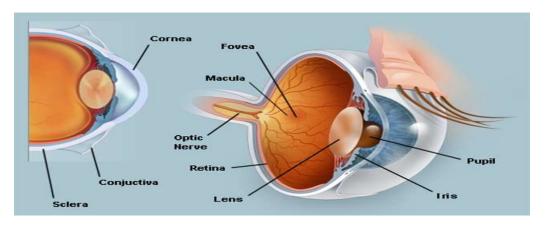

Figure 1: Anatomy of the eye (WebMD, 2015)

In biometrics, the iris belongs to the physiological traits of human being, and its function is to control the amount of light entering through the pupil. Major applications of iris recognition systems include criminal investigation, eye tracking, immigration and border controls, access and security applications, and so on. (Daugman, 2009). Like other biometric recognition system, iris recognition system is composed of the image acquisition, feature extraction, template formation and database, matching and decision-making stages (Minaee *et al.*, 2016). According to Schmidhuber (2015), the classification of image data is largely based on the description, texture or similarity of the trait in question. Different robust machine learning techniques have been used for many classification tasks such as: Linear Regression, Random Forest, Support Vector Machine (SVM), Linear regression, Logistic regression, Naive Bayes, Linear discriminant analysis, Decision trees, K-nearest neighbor algorithm and so on.

However, recently deep learning approach have demonstrated remarkable success in multiple domains including computer vision, natural language processing, speech processing and in various biometric systems (Nguyen *et al*, 2018). According to Favio (2022), deep learning is a subfield of machine learning, a new approach on learning representations from data that puts emphasis on learning successive "layers" of increasingly meaningful representations. It is a modern update to Artificial Neural Networks that are concerned with building of large and complex neural networks. Deep learning techniques are effective in learning complex features from data, such as images, texts, audio, and videos. Its learning process can be supervised, semi-supervised or unsupervised depending on the data structure. The technique allows computational models that are composed of multiple processing layers to learn representations of data with multiple levels of abstraction. These layered representations are learned via models called "neural networks", structured in literal layers stacked one after the other. Figure 2 depicts the simple neural and deep learning neural networks respectively.

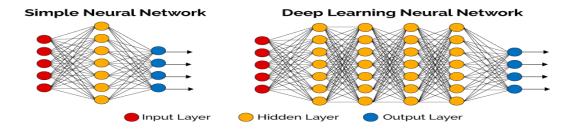

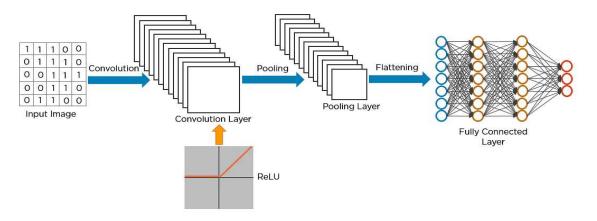

Figure 2: Showing the simple neural and deep learning neural networks Source: (Favio, 2022)

Deep learning algorithms have been used to solve classical artificial intelligence problems with the main goal of learning high level abstractions from data (Sa *et al.*, 2016; Khalifa *et al.*, 2019). Popular deep learning techniques include: Artificial Neural Network (ANN), Convolutional Neural Network (CNN), Recurrent Neural Networks (RNNs), Long Short-Term Memory Networks (LSTMs), Stacked Auto-Encoders, Deep Boltzmann Machine (DBM), and Deep Belief Networks (DBN). Meanwhile, much attention is been given to Convolutional Neural Networks (CNN) because of its effectiveness in computer vision task such as image analysis and classifications. It has become one of the most appealing approaches in the recent time. It is very suitable for this work, hence it is considered.

According to Muhammad et al, (2022), CNN, also known as ConvNet, is one of the best neural networks for classification, segmentation, natural language processing (NLP), and video processing. Its application has become most demanding due to its ability to learn features from images automatically, involving massive amount of training data and high computational resources like graphic processing units (GPUs). According to Senan et al., (2020), the reason behind better performance of CNN is due to its ability to work on raw data without having prior knowledge of the data. The architecture of CNN is very similar to the ordinary Neural Networks, they are made up of neurons that have learnable weights and biases. Acording to Biswal (2022), a convolutional neural network is a feed-forward neural network (FNN) that is generally used to analyze visual images by processing data with grid-like topology. When using CNN algorithm for image classification, the image is usually fed directly to the convolutional neural networks, then the algorithm extracts the best features of the image.

CNNs are regularized versions of multilayer perceptron. Each neuron in one layer is connected to all neurons in the next layer. This full connection of these networks makes them prone to over-fitting. However, pooling process is a down-sampling operation that reduces the dimensionality of the feature map. According to Mandal (2021), the CNN consists of multiple hidden layers of structural parameters that help in extracting information from an image. The architecture is divided into four important layers, namely: the convolution layers, ReLU layer, pooling layers, and fully connected layers (O'Shea and Nash, 2015; Muhammad et al., 2022). Figure 3 shows CNN architecture.

2. STATEMENT OF PROBLEM

Iris recognition has been adjudged one of the most reliable forms of biometric technology, as a result of its unique patterns, stringency to forgery and robustness against spoof attacks (Sundaram et al., 2011; Elgamal et al., 2013; Shah and Shrinath, 2014). Iris image is well known for high precision and possesses a good resistance to replication (Kong et al., 2010; Shah and Shrinath, 2014). Its unique patterns do not change over time, thus making it a perfect and reliable means of recognition (Dehkordi and Abu-Bakar, 2015). However, studies have revealed that inadequate classification sorts and methods leading to inaccurate matching and classification has characterized its processes in many authentication and identification applications. Various methods proposed to address these challenges as reported in (Hollingsworth et al., 2011; Thiyaneswaran & Padma, 2012; Oyedotun & Khashma, 2016; Arsalan et al., 2017; Zhao & Kumar, 2017; Tapia & Aravena, 2017; Bobeldyk & Ross, 2019; Khalifa et al., 2019) are majorly based on single iris image classification, and major drawbacks of these approaches are insufficient learning input for proper classifications. To the best of our knowledge, few works that considered both left and right iris classification using traditional neural networks suffers a trade-off between accuracy and computational complexity coupled with high error rate. Hence, this work presents an enhanced classification model based on convolutional neural network (CNN) to proffer solutions to the challenges of the convetional approaches.

3. METHODOLOGY

3.1 The Research Design

To achieve the objectives of the work, the architecture of the classification model was first designed as depicted in figure 4. The model was designed based on the CNN, composed of five major components: the image processing, the convolution layer feature maps, the rectifier linear unit, pooling layer features maps and the fully connected layers (classification layers). The image preprocessing in the model architecture involves feature extraction from the image pixels.

In the convolusion layer, the convolution operations are performed by combining the image with a feature detector or learnable filter in order to extract data from neighbouring pixels.

The rectified linear unit (ReLU) is used to increase the non-linearity of the output image in the convolution layer after the required features have been filtered. Pooling is applied to the output from the ReLU to extract the most meaningful information. In order to avoid over fitting of the learned features, a down-sampling method (max pooling) was used to reduce the size of the pooled image, and the number of values as input are forwarded to the classification layer containing fully connected layer of neurons for image classification.

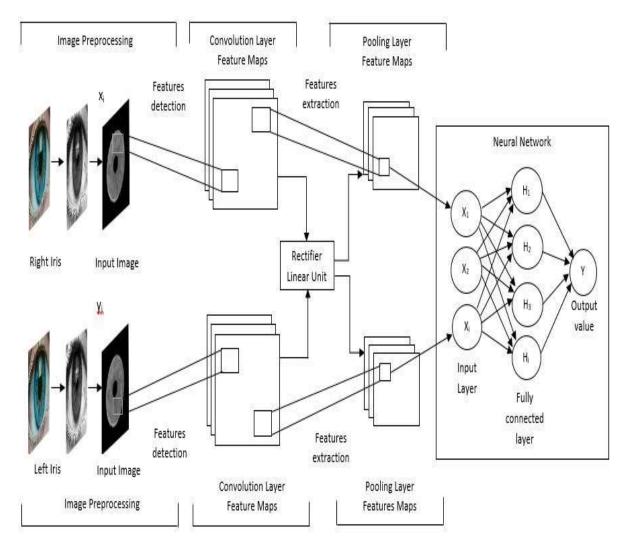

Figure 4 The Architecture of the Classification Model

(1)

The process is mathematically presented in equation 1:

 $Preprocessed \ image \rightarrow (Conv \rightarrow ReLU \rightarrow Pool) * M \rightarrow (FC \rightarrow ReLU) * K \rightarrow FC \rightarrow Classification$

Where:

- 1. Conv: is the Convolutional Layer
- 2. ReLU: is the Rectified Linear Unit
- 3. FC: is the Fully Connected Layer
- 4. M and K: are numbers representing the number of times each operation is performed.

3.2 Image Acquisition

The data for the work was acquired from the CASIA-Iris-Lamp dataset (http://biometrics.idealtest.org, 2010). The CASIA-Iris-Lamp dataset is a robust iris feature representation. The iris images are 8-bit gray-level JPEG files, collected under near infrared illumination. A total of 16.163 iris data was considered in the research work. The training set contained 12,931 iris images, while the test set contained 3,232 data. 20 iterations were passed on the model to determine the accuracy of the model.

3.3 Image Processing

The image processing involves salient feature extraction, segmentation and normalization of the acquired images. The image acquired was enhanced through segmentation of the required region of the trait, followed by normalization process to form a fixed pattern in polar coordinates. At the segmentation phase, the separation of the iris from the whole eye area took place. At this stage, the position of the upper and lower eyelids was determined, as well as the exclusion of areas covered by the lashes. Iris segmentation acts directly on the image of the iris, seeking the maximum normalized standard circle along the path, a partial derivative of the blurred image relating to the increase of the circle radius.

The center of the coordinates and the radius of the circle were sought for, and edge of the iris was determined. The purpose of the segmentation stage is to enhance the image in order to produce high clarity iris image that serves as input to the classification model. The enhancement reduces computational complexity of the model with a goal to avoid decline of matching performance. For the segmentation process, circular Hough Transform was applied to detect the boundaries of the iris and the pupil. This also involves performing Canny Edge detection to generate an edge map (Sangwan & Rani, 2015). The Canny Edge detection contains five stages: Smoothing, Finding gradients, Non-maximum suppression, double thresholding, and edge tracking through hysteresis (Jayachandra & Reddy, 2013). The normalization process is the transformation of the localized iris to a defined format in order to allow comparisons with other iris codes into an iris template (binary code). The number of values as input are forwarded to the classification layer.

3.4 Matching Process

This process establishes correspondences between the set of the images acquired. The approach involves detecting a set of interest points each associated with image descriptors from iris image. The performance of the matching methods is based on the properties of the underlying interest points and the choice of associated iris image descriptors (Tyagi, 2019). Table 1: shows the sampled interest point scores.

	Righ	t iris	Left	t iris	Tx	Ту
Identity	x _i (mm)	xi (mm)	yi	y (mm)	(mm)	(mm)
			(mm)			
1	10.1	10.3	10.3	10.4	10.2	10.35
2	10.2	10.5	11.5	11.6	10.35	11.55
3	11.0	11.4	11.5	12.0	11.2	11.75
4	12.2	12.3	12.5	12.8	12.25	12.65
5	11.5	12.0	12.1	12.6	11.75	12.35

Table 1: Sampled interest point scores

3.5 Performance Evaluation

Sensitivity, specificity and accuracy were used to evaluate the performance of the classification model coupled with the confusion matrix report.

Values of TN, TP, FN and FP were used to calculate the performance metrics considered.

Sensitivity =
$$\frac{TP}{TP+FN} = \frac{1602}{1602+14} = 0.9913$$
 (99.13%) equation 2

Specificity =
$$\frac{1}{TN+FP} = \frac{1}{161} = 1.0000 (100\%)$$
 equation 3

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} = \frac{1602 + 161}{1602 + 1616 + 0 + 100} = 0.9957 (99.57\%)$$
equation 4
(11)

Where,

- 1. TP represents the True Positives: These are cases in which the model predicted YES (the images are left irises), and they are actually left irises.
- 2. TN represents the True Negatives: The model predicted NO for left irises, and they are actually NOT left irises.
- 3. FP represents False Positives: The model predicted YES for left irises, but they are actually NOT left irises.
- **4.** FN represents False Negatives: The model predicted NO for left irises, but they are actually left irises. Table 2 showed the confusion matrix report for the classification of the iris images considered.

Actual Class	Predicted Class	
	Left Iris	Right Iris
Left Iris	TN = 1,616	FP = 0
Right Iris	FN = 14	TP = 1,602

Table 2: Confusion Matrix Report for Classification of Iris Images

4. DATA PRESENTATION

4.1 Experimental Setup

The derived pooled feature map in equation (1) is flattened into a long vector to serve as input layer for the neural network with fully connected neuron layers for the image classification. During the experiment, the dataset was fed into the Anaconda platform installed for the purpose of the work. The software is an open-source application for management of multiple Python versions on one computer. Anaconda provides a large collection of highly optimized, commonly used data science libraries to carry out experiments. It has a powerful IDE with advanced editing, interactive testing, debugging and introspection features called Spyder. Figure 5 presents the Anaconda Navigator (Individual Edition (Distribution) Interface).

A specific internal environment (tensorflow) was created to manage the IDE and python libraries (Theano, TensorFlow, Keras). Figure 6 presents the IDE and Python Libraries Environment

Figure 6: IDE and Python Libraries Environment

Figure 7 presents the implementation in Spyder IDE and describes the following three major aspects: the dataset was fed into the platform by setting it as working directory. The dataset was splitted into two folders (*training_set, test_set*) within the working directory using 80/20 ratio (that is 80% of the total dataset for training the model and the remaining 20%) for validating the model. Since this work focuses on binary classification of the left and right iris image, two subfolders (*left, right*) were created within the *training_set* and *test_set* folders to hold the two classes of labelled iris images (left irises, right irises). Secondly, the CNN model was built using Python programming language which supports scientific/numeric computing and effective integration of systems, and Thirdly, a console in figure 7 shows the classification report as the model is trained and validated with the dataset.

5. RESULTS AND FINDINGS

This work adopts the scaling law ratio for training set composed of 80% of the total dataset, while the remaining 20% is allocated for the test set. 20 iterations were passed on the model to determine the accuracy of the developed model. The snapshot of the the iteration process is shown in Figure 8.

Figure 8: Iteration Process

At the 20th iteration level, the classification report gave a training accuracy of 99.50% with validation accuracy of 99.57% while a training loss of 1.86% was achieved with validation loss of 2.59%. A difference of 0.07% was achieved between the training and validation accuracy which shows that the model was able to overcome over-fitting by effectively closing the gap between the training and validation accuracy.

Table 3 showed the classification report for the training and validation process. Figure 9 presents a graph of the Training and Validation Loss while figure 10 presents the Training and Validation Accuracy using matplotlib in python.

Figure 11 showed the snapshot of confusion matrix report
--

Figure 11: Snapshot of Confusion Matrix Report

Interpreting the confusion matrix report, the model reported O false positives (FP) and 14 false negatives (FN) on the test set. This surfice to say the model correctly predicted all images belonging to right category as right irises while it wrongly predicted 14 images belonging to the left category. By implication, there was higher accuracy on the right iris compared to the left iris.

6. CONCLUDING SUMMARY AND CONTRIBUTION TO KNOWLEDGE

This work presented an efficient classification model based on CNN for the classification of both left and right iris images to proffer solution to the inadequacies of the classification sorts and the challenges of the single mode classification techniques. Data for the work acquired was segmented and normalized and were later fed into the Anaconda model building platform installed for the work. The classification model developed was tested and had an accuracy of 99.57% which is relatively an improvement over existing iris feature detectors and classification techniques. The confusion matrix reported 0 false positives (FP) and 14 false negatives (FN) on the test set. The shows that the model correctly predicted all images belonging to right category as right irises while it wrongly predicted 14 images belonging to the left category.

By implication, there was higher accuracy on the right iris compared to the left iris. Based on the performance of the model presented, the research work has established that CNN based model as an improvement compared to other models in the domain. The current model in no small measure will increase the efficiency of biometric security applications and assit eye medical practitioners. Researcher in the future work will consider the case of multiple classes and larger database.
